

Docket No. AUS9-2000-0458-US1

ABSTRACT OF THE DISCLOSURE

LOCALE INDEPENDENT MESSAGE MANAGEMENT FOR MULTI-NODE APPLICATION SYSTEMS

5

A method, system, and computer program product for managing results in a locale independent manner in a multi-node networked data processing system is provided.

10 In one embodiment, a first node sends a command request to a second node. The command request contains a command and a locale in which the text of the result is desired. The first node receives the results of execution from the command request sent to and executed on the second node.

15 The result generated by the second node in response to the command request includes one or more messages, wherein each message contains a unique message identifier, locale in which its associated text is stored, and text associated with the message. Responsive

20 to a determination that the locale of the message text is in a locale different from a desired locale, the first node replaces the message text contained within the result with message text corresponding to the desired locale to produce a modified result and sends the

25 modified result to the requesting client node.
